

Nevio Vesic

Senior software / protocol engineer

Rijeka and Zagreb, Croatia · nevio@inorbit.hr · inorbit.hr · github.com/0x19 · www.linkedin.com/in/neviovesic/

Available from October 2026 for contract or full-time work: protocol, infrastructure and distributed systems, in Rust and Go.

SUMMARY

Twenty years in the unglamorous half of the stack: voice servers and SMS gateways first, then anycast networks carrying real-time traffic at sixty gigabits, then rollups, bridges and indexers, and most recently the RPC infrastructure in front of a hundred-odd blockchain networks. Ten of those years in Go, and as much Rust lately. Whatever I build for the fun of it ends up here too.

SELECTED WORK

- Early work on a Layer 1 to Layer 7 network with a distributed team, carrying over 60 Gbps, which secured a \$3M+ annual contract and opened the following investment round.
- One of the first WASM ports of a Layer 2 blockchain node in Go.
- An optimistic EVM rollup written entirely in Go, from inception to deployment.
- The first Go Solidity AST and IR parser, control-flow graph construction included.
- A cross-chain liquidity bridge between Ethereum and Bitcoin on multi-party computation and threshold ECDSA.
- A cross-chain EVM indexer that streams an entire blockchain dataset in under ten hours.

EXPERIENCE

Tenderly · Software engineer (L5)

2024–2026 · Remote

Developer infrastructure for Ethereum — simulation, debugging and the systems behind them, at production volume. Backend work in Go and Rust on the systems that carry it. The contract ended in September 2026.

(Un)Pack · Founder

2023–2024 · Remote

My own product: a platform that pulls Ethereum contracts apart at scale — source, AST and IR, bytecode, control-flow graphs — with a discovery service over GraphQL that used language models to say what a contract does and whether it looks like a rug pull. Switched off when the Tenderly work began, because running it cost more than it earned. The libraries stay public.

- Designed, built and ran it alone: crawler, storage, analysis, API and the bill.
- solgo — the first Solidity AST and IR parser in Go, with control-flow graph construction; used by others since.
- A crawler that peaked above 30k requests a second against the chain, feeding one to one and a half terabytes a day into Postgres and ClickHouse.
- Token pricing from pool reserves directly, without Chainlink or a third-party API.

Eiger · Senior software / protocol engineer

2022–2024 · Remote

Protocol work across several chains, from research to deployment: a proprietary EVM-compatible optimistic rollup taken from inception to production, one of the first WASM ports of a Layer 2 node in Go, and a cross-chain liquidity bridge between Ethereum and Bitcoin built on multi-party computation and threshold ECDSA. Led teams of up to five, ran the research, and wrote the grant proposals that funded some of it.

InOrbit · Owner

2018–present · Croatia

The company the B2B work runs through; Subspace, Eiger and Tenderly were all engaged this way.

Subspace · Senior software engineer

2018–2022 · Remote · Los Angeles

A network built for traffic that cannot wait. I wrote the user-space services sitting between the kernel and the control plane, and some of the kernel side itself — IP filtering, packet rewriting, network-card caching, map management. Co-built the first version of the TURN anycast network, live in over 150 points of presence, and the first SIP anycast network on Kamailio and FreeSWITCH; also the Elixir control plane that provisioned tunnels and billed usage from a geo-aware distributed database.

- One of the first three engineers. A Layer 1 to Layer 7 network built in six months for the MENA region, carrying over 60 Gbps from the start; it secured a contract above three million dollars a year and the next funding round.
- Co-conceived and co-built the first global TURN anycast network, over 150 points of presence, and the SIP anycast network on Kamailio.
- User-space services between the kernel and the control plane, and the kernel side itself in eBPF: IP filtering, packet rewriting, NIC caching, map management. A patent-pending contribution on the eBPF design.
- The Elixir control plane that took customer API requests and turned them into IPv4 tunnels, with usage billing from a geo-aware distributed database.

The TelAPI platform after its acquisition, as Zang Cloud and then Avaya CPaaS. Go microservices on the platform, then architecting the next generation of its front end and running the team that built it, including the security and compliance side — code scanning, HIPAA, GDPR, SOC.

- Led the front-end services team: planning, unblocking, delivery.
- Architected the next generation of the CPaaS front end (React, Node.js, Go, Kubernetes, GCP, AWS).
- Owned the security side of it: code scanning and HIPAA, GDPR and SOC compliance work.

TelTech Systems · TelAPI · Senior software engineer

2014–2016 · Remote · New York

Telecom at the protocol level: voice servers on FreeSWITCH and Kamailio, an SMS stack over SMPP with its SMSC and SMSE sides, phone-number and carrier services, and the full rewrite of those services from Python to Go. Consumer products on the same plumbing, spoofcard.com and tapeacall.com among them.

- Voice servers on FreeSWITCH and Kamailio; an SMS stack over SMPP with its SMSC and SMSE sides; phone-number and carrier services.
- The full rewrite of the services from Python to Go.

TelAPI Adriatica · Director

2013–2015 · Croatia

The Croatian branch, and two engineers in it. Closed when Avaya acquired the parent.

EARLIER

2011–2014 TelTech Systems, web application developer — the CPaaS front end in Zend, its documentation and API explorer; 2011 ClkClk, web developer — the company's SaaS, then its internal administration from scratch; 2010–2011 Adria24, web developer — the internal booking system of a tourist agency, front and back; 2009–2010 In-tech, WebFactory, lead web developer — a book e-commerce platform; WordPress; 2007–2008 Skin29, Design Strategist, web developer — a CMS later used by several large Croatian companies.

OPEN SOURCE

solgo 2023	A Solidity parser in Go that turns contract source into a structured form you can analyse — the base for detectors, ABI work and standards discovery. github.com/unpackdev/solgo
sourcify-go 2023	A Go client for the Sourcify API: verify a contract, fetch its metadata and sources, check what a chain already knows about an address. github.com/unpackdev/sourcify-go
fdb 2024	A high-performance transport layer in front of embedded key-value databases such as MDBX, for the reads a node or an indexer cannot wait on. github.com/unpackdev/fdb
solc-switch 2023	Manages every Solidity compiler version at once and compiles with the right one, concurrently, instead of juggling toolchains by hand. github.com/0x19/solc-switch
go-clickhouse-orm 2023	Model and migration support for ClickHouse in Go, so an analytics schema is versioned like any other part of a service. github.com/0x19/go-clickhouse-orm
gotostruct 2015	Turns a JSON object into a Go struct, as a library and as the public tool that ran at jsonstruct.com . Written because I was tired of doing it by hand. github.com/0x19/gotostruct
disposable 2016	A JSON and gRPC API that answers one question — is this a throwaway email address? Small, public, and quietly used by strangers ever since. github.com/0x19/disposable
goesl 2015	A FreeSWITCH Event Socket library for Go. Written in 2015 and still forked and shipped by other people — telephony was the first system I had to keep up. github.com/0x19/goesl

LANGUAGES AND EDUCATION

English, Croatian, Bosnian, Serbian, Slovenian. Secondary school, 2000 — 2003. Everything since, self-taught on the job.
